

DESI Loa | a slice through the observed cosmic web

Same galaxies, three views · 20 Mpc thick equatorial slab · RA 130°–230° · $0.15 \leq z < 0.55$
Positions use observed redshifts and Planck18 distances; redshift-space distortions remain.

● Void ● Sheet ● Filament ● Knot

Provisional environmental inferences · real-DESI coverage unverified
Training-mock mismatch grows above $z \approx 0.35$, severe at $0.45 < z < 0.55$. Trends are not evidence of physical evolution.
Lower-redshift results are not automatically certified. Morphology is not an independent calibration test.

A closer view | positions, environments and ambiguity

Fixed geometric window: transverse ± 180 Mpc, radial-plane 650–950 Mpc; same 20 Mpc slab
No confidence cut, class balancing, smoothing or invented filament connections.

Training-mock mismatch grows above $z \approx 0.35$, severe at $0.45 < z < 0.55$. Trends are not evidence of physical evolution.
Lower-redshift results are not automatically certified. Morphology is not an independent calibration test.

The web is inferred probabilistically

Same close-up, all four probabilities · bright points have greater probability of that environment
Void denotes a galaxy's local environment, not a map of empty volume.
