Why the two Loa selections describe different populations — property wedge
Old selection: fixed mass cut + nearby ceiling
Reconstructed 90% limit
Old raw FSF ≥9 → physical ≥9.305
Intended physical 10⁹ reference
log₁₀ stellar mass: FastSpecFit, h=0.704
Redshift z
Current selection: brightness-limited, z=0.15–0.55
log₁₀ stellar mass: CIGALE CG15
Current estimated 90% limit
10⁹ reference (not complete)
Redshift z
Different mass estimators are explicitly separated. Old completeness uses the pre-mass-cut main-BRIGHT parent.
The z=0.15 boundary reflects mock-label validity, not a stellar-mass completeness threshold.
