

Galaxy properties versus current Loa environment

Saved CIGALE CG15 properties · RA 120–160°, Dec 14.5–30.6°, $0.20 \leq z < 0.30$

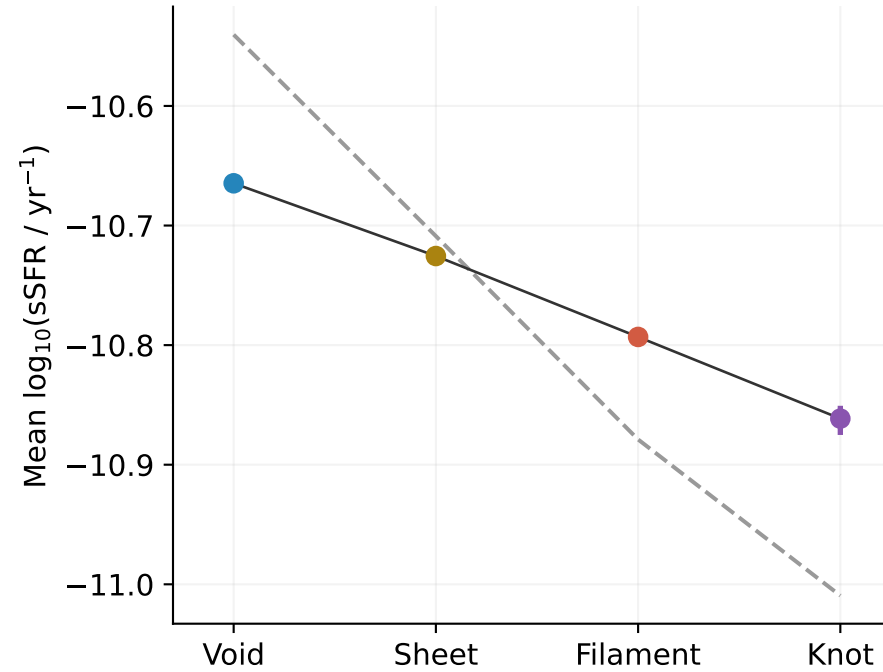

Grey dashed: raw probability-weighted mean. Coloured: common z mix (mass); common z + CIGALE mass mix (sSFR / fraction).

Intervals: 16–84% sky-block bootstrap; property errors and model-transfer systematics are not propagated.

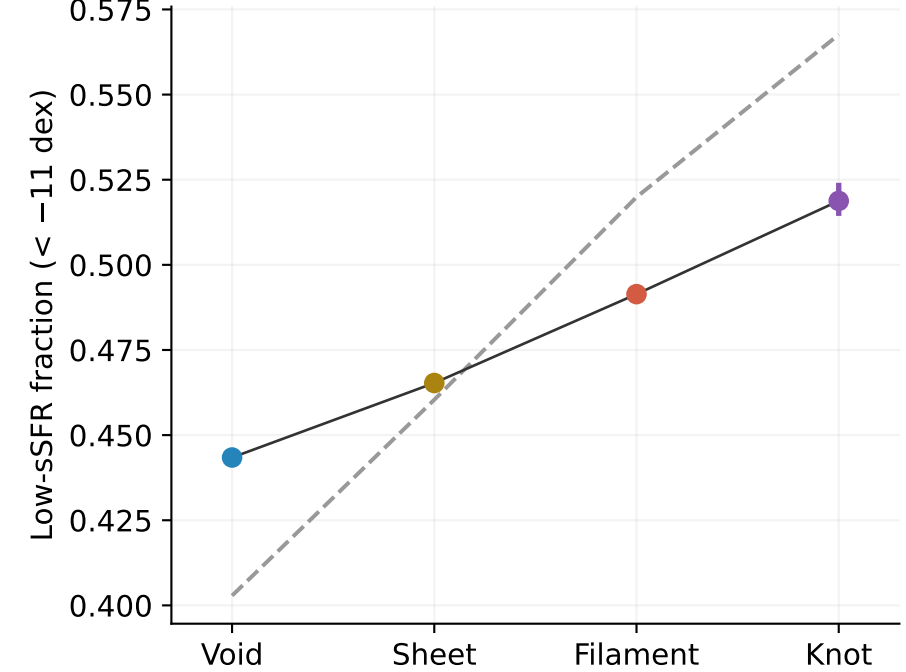

N=102,634 retained; 4 strata

N=102,220 retained; 32 strata

N=102,220 retained; 32 strata

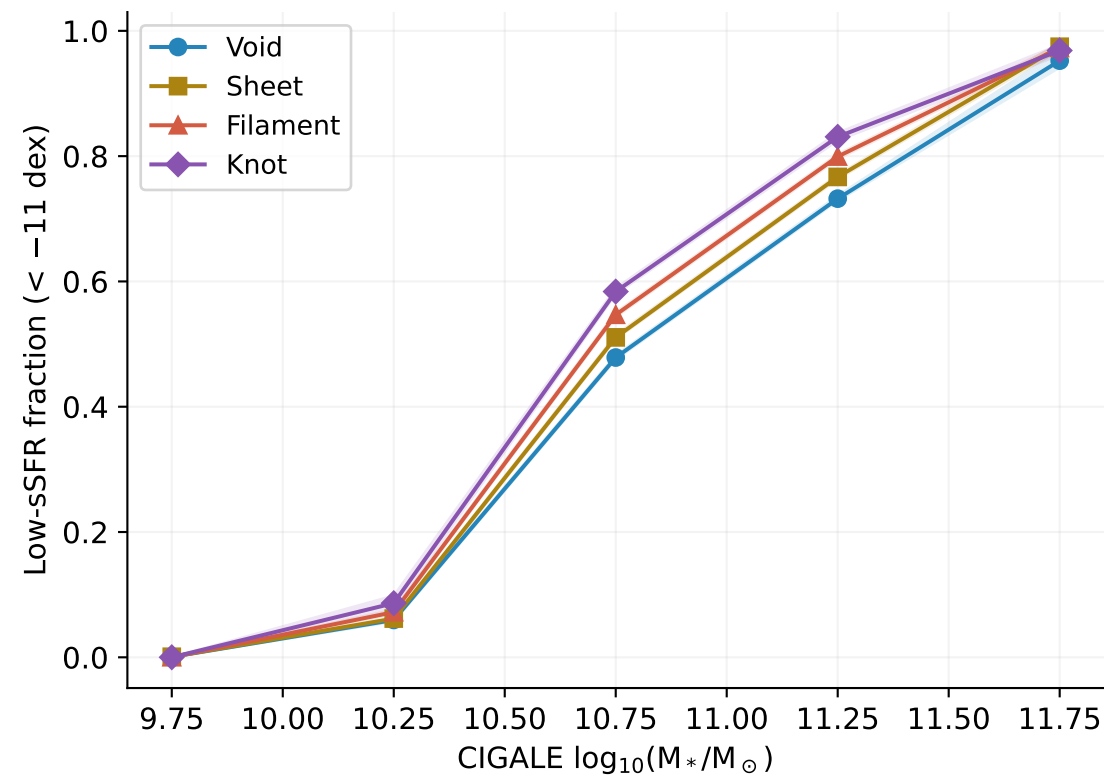

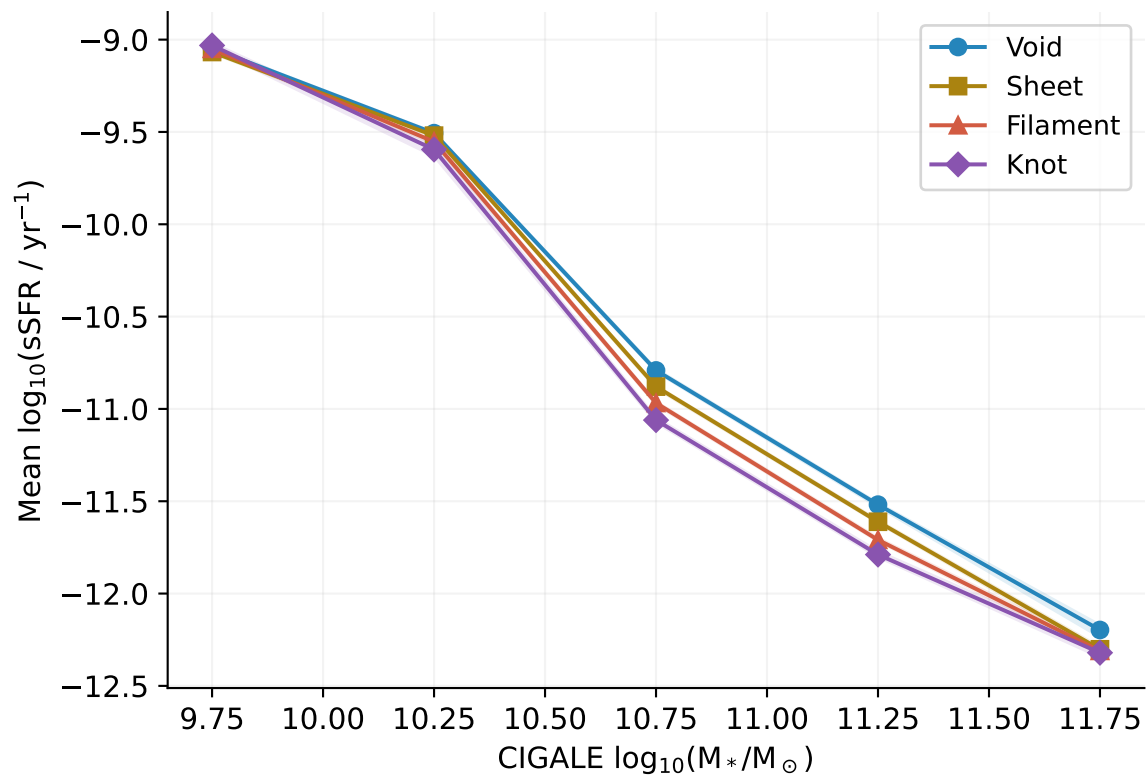

Provisional current-VAC environments; real-DESI coverage unverified, including this low-z wedge.
Property relationships are descriptive checks, not calibrated true-class population estimates or causal effects.

Does the relationship survive at fixed stellar mass?

Current environment probabilities · each mass bin shares a common redshift distribution

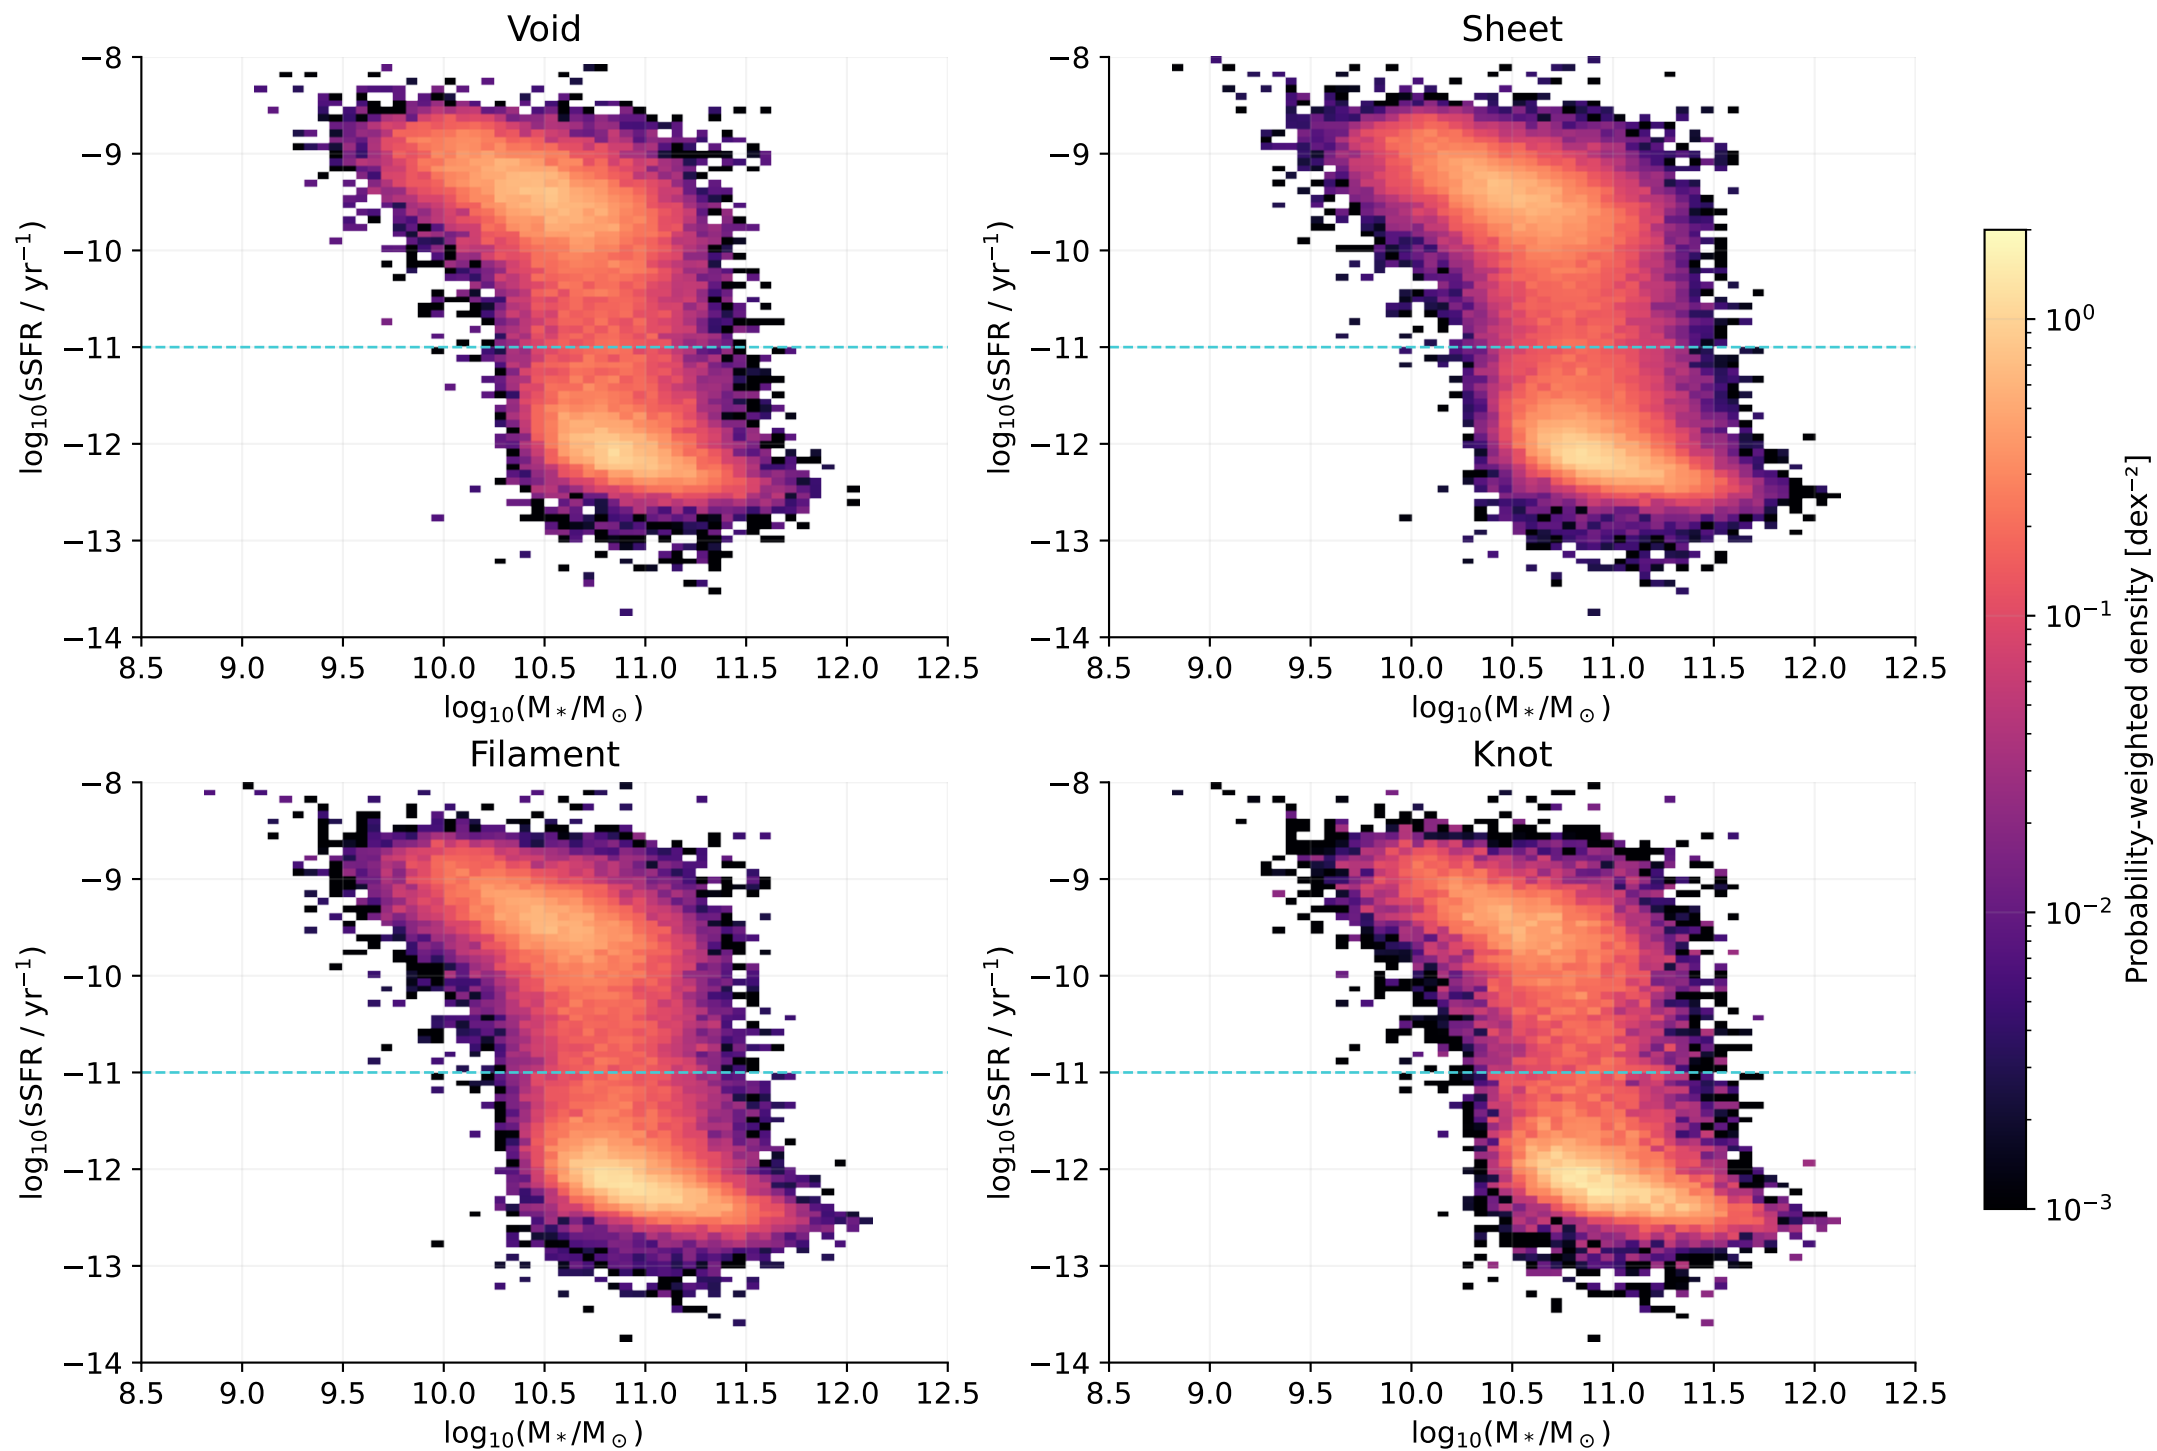

Shading: 16–84% sky-block bootstrap; bins without common support are omitted.

Provisional current-VAC environments; real-DESI coverage unverified, including this low-z wedge.
Property relationships are descriptive checks, not calibrated true-class population estimates or causal effects.

Stellar mass and specific star formation

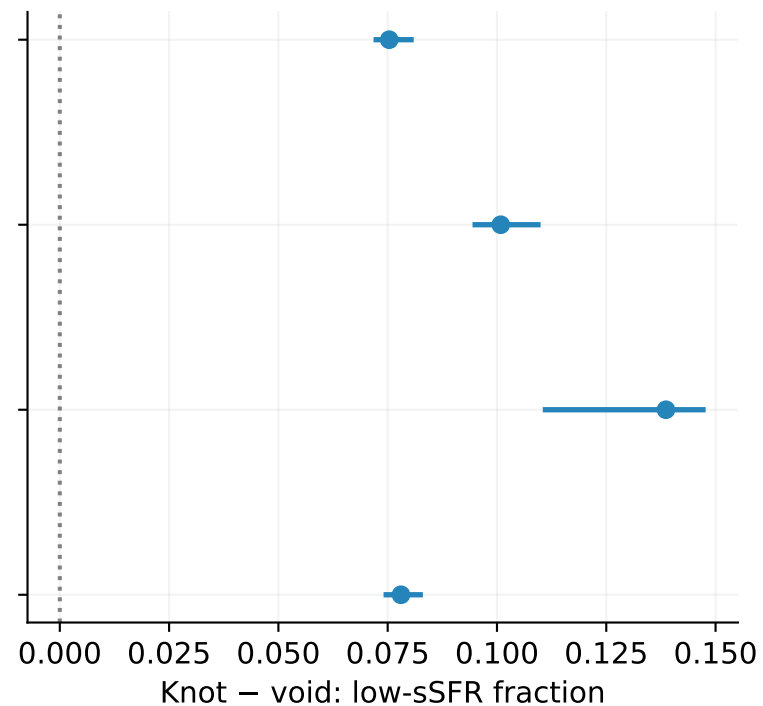

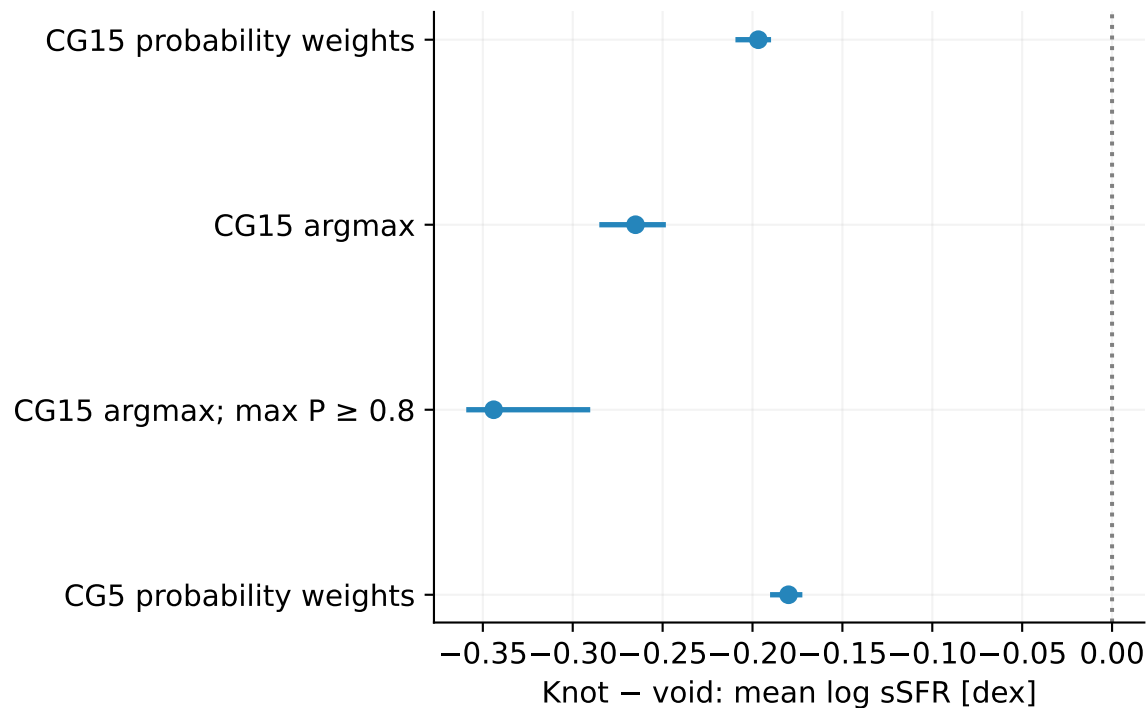

Same galaxies in each panel, weighted by their current environment probabilities
Density normalized by total class probability weight; identical colour scales. These are observed selected-sample distributions.

Provisional current-VAC environments; real-DESI coverage unverified, including this low-z wedge.
Property relationships are descriptive checks, not calibrated true-class population estimates or causal effects.

Knot – void contrast: membership and property checks

All comparisons control redshift and stellar mass; retained supports differ by estimator
Intervals: 16–84% spatial bootstrap. High-confidence selection is a sensitivity check, not the primary sample.

Provisional current-VAC environments; real-DESI coverage unverified, including this low-z wedge.
Property relationships are descriptive checks, not calibrated true-class population estimates or causal effects.
